Despite dramatic drops in overall incidence and mortality, striking disparities remain

Colorectal cancer (CRC) is the third most commonly diagnosed cancer in both men and women. In 2017, there will be an estimated 95,520 new cases of colon cancer and 39,910 cases of rectal cancer diagnosed in the United States. While the numbers for colon cancer are fairly equal in men (47,700) and women (47,820), a larger number of men (23,720) than women (16,190) will be diagnosed with rectal cancer. Incidence rates are highest in Alaska Natives (91 per 100,000) and African Americans (49 per 100,000) and lowest in Asian Americans and Pacific Islanders (32 per 100,000).

An estimated 27,150 men and 23,110 women will die from CRC in 2017. Unfortunately, reliable statistics on deaths from colon and rectal cancers separately are not available because almost 40% of deaths from rectal cancer are misclassified as colon cancer on death certificates.

CRC incidence rates continue to decline in people 50 and older, dropping by 32% just since 2000. This trend is thought to be largely a result of screening, which can prevent CRC by detecting and removing precancerous polyps. Incidence rates are dropping fastest in people ages 65 and older and for tumors located in the distal colon, while the drop is slowest for people ages 50 to 64 and for rectal tumors. For example, there was only a 9% decline in the incidence of rectal tumors in men ages 50 to 64 and no decline in women that age compared to 38% and 41% declines in men and women, respectively, ages 65 and older.

Incidence rates in people 50 and older are dropping in every state, with the decline exceeding 5% annually from 2009 to 2013 in seven states (Nebraska, Maine, Rhode Island, Delaware, Massachusetts, South Dakota, and California). Notably, declines are slowest in states with the highest incidence (e.g., Kentucky, Mississippi, and Louisiana).

In stark contrast to the CRC incidence trends in those 50 and older, incidence rates among people younger than 50 continue to rise, increasing by 22% from 2000 to 2013. While the reasons for the increase have yet to be confirmed, factors thought to play a role include increasing rates of excess body weight, as well as changes in lifestyle patterns that precipitated the obesity epidemic, like unhealthy dietary patterns and a sedentary lifestyle.

Similar to incidence patterns, CRC death rates decreased by 34% in people 50 and over during 2000-2014 but increased by 13% in those under 50.

National Health Interview Survey (NHIS) data indicate that from 2013 to 2015, screening with any guideline-recommended test increased from 53% to 58% in those ages 50 to 64, from 65% to 68% in those 65 and older, and from 59% to 63% in both age groups combined. This rise, which follows a plateau in screening between 2010 to 2013, translates to an additional 3,785,600 adults (>50 years) screened in 2015. If screening prevalence remains at the 2015 rather than the 2013 level, an estimated 39,700 additional CRC cases and 37,200 deaths will be prevented through 2030.

The authors of the report conclude that reducing inequalities in colorectal cancer and accelerating progress can be achieved by ensuring equitable, high-quality treatment for all patients, effecting pervasive lifestyle modifications, and increasing initiation of screening at age 50 for people at
average risk and earlier for those with a family history of CRC or advanced adenomas.
